

Introduction to CoP17 Prop. 8 - CoP17 Prop. 12 Pangolins

There are eight species of pangolins, all in the genus Manis, following CITES standard nomenclature. Four are collectively distributed in South, East and Southeast Asia, while four others are native to sub-Saharan Africa. All pangolins are currently listed in Appendix II, with wild-caught Asian pangolins traded for primarily commercial purposes being subject to zero export quotas. The five proposals CoP17 Prop. 8 - CoP17 Prop. 12 seek to transfer all pangolin species to Appendix I.

High demand in Asia has clearly led to significant declines in populations of pangolins, in particular M. pentadactyla and M. javanica and an increase in demand for other Manis species, both in Asia and in Africa, to increase. Detailed population data on some species are scarce, resulting in insufficient information to determine if these species meet the biological criteria for inclusion in Appendix I. However, there are indications that populations have shown significant declines, with high levels of illegal trade recorded, and continual, and in many cases increasingly heavy demand and harvesting. While comparatively little trade in Asian or African pangolins has been reported to CITES since 2000, large volumes of illicit trade have taken place, involving a minimum estimate of some 17,000 pangolins globally each year. In addition to the large shipments being seized in East Asia, originating from Southeast Asia, there are increasingly frequent large shipments of scales being seized coming from Africa.

It is important to note that all pangolins in trade are wild sourced: there are no reliable reports of commercial captive-breeding which is extremely difficult owing to the species' breeding biology and the extreme difficulties in keeping them alive in captivity. Pangolins are vulnerable to overexploitation owing to their low reproductive rates (producing only one or two offspring per year).

Concern over sustainability of trade reported to CITES, particularly in skins, led to the inclusion of Asian pangolins in various phases of the Review of Significant Trade (RST) process in 1988, 1992 and 1999, with recommended actions being made to various range States to control trade. The African species M. tetradactyla, M. tricuspis, M. gigantea and M. temminckii were also included in Phase IV of the RST in 1999 but were subsequently eliminated from the process. M. gigantea and M. tricuspis were again selected for the RST as species of priority concern in 2013.

Despite going through the RST processes multiple times, and having the zero quota with Appendix II, illegal trade seems to have continued unabated for the Asian species. So far these processes have failed to provide any notable protection from unsustainable harvest and trade of these species and an Appendix I would be a precautionary measure proportionate to the anticipated risks to the species.

Inclusion of all Manis species in CITES Appendix I could greatly enhance efforts to safeguard pangolins and support regulatory control mechanisms by non-range States, by placing an overall higher degree of international protection. However, this can only happen if national legislation provides for higher fines and punitive measures for illegal trade in Appendix I-listed species.

CoP17 Prop. 8 [Bangladesh] and CoP17 Prop 9 [India, Nepal, Sri Lanka and United States of America] Transfer of Indian Pangolin *Manis crassicaudata* from Appendix II to Appendix I

The Indian Pangolin *Manis crassicaudata* was classified as globally Endangered by the IUCN in 2014, owing to the immense threat that trade poses across its range in five Indian subcontinent countries, although it may be extinct in Bangladesh owing to illegal hunting for trade. Since 2000, seizure data indicate that illicit international trade in at least 8000 *M. crassicaudata* took place, while it is likely to become more heavily targeted as other species decline: close to 600 000 Asian pangolins were in international trade from 1977 to 2012.

There are few data on the population status of this species, though it is believed to have been extirpated from some of its range in Bangladesh and populations appear to have declined markedly due to poaching in parts of Pakistan. Very little is known on the population in India which is the majority of the species' range, although it is believed to have been reduced. This is despite national legislation protection from hunting and trade in all range States. International demand for pangolins is believed to be increasing and, despite the lack of detailed information, the level of extractive pressure this species is experiencing is such that a listing is likely to be in the best interest of the conservation of the species.
